ABSTRACT

Stress perception and plant response occurs via signal transduction pathways, regulates expression of several classes of stress responsive genes (srq-genes). The products of srq-gene include chaperones, osmotins, anti-freeze proteins, mRNA binding proteins, enzymes involved in osmolyte biosynthesis, water channel proteins, sugar and proline transport proteins, detoxification enzymes, a variety of proteases, proteins and protein kinases/ or receptor-like kinases (RLKs). Out of these srq-gene products, protein kinases (RLKs) are transmembrane proteins and play an important role in optimizing plant responses under different types of stress. Protein kinases (RLKs) make up a large super-family of homologous proteins, which are subdivided within the two super-family (i) Protein-serine/ threonine kinases and (ii) Protein-tyrosine kinases. Plant RLKs are further classified into the six different classes (S-domain, LRR, TNFR, WAKs, PR, LecRLK), which performed different functions in plants. This review explored how stress-specific ‘ligands’ of different types of RLKs coordinately control various molecular events under stress conditions.

Key Words: Abiotic and biotic stress, Signaling, Receptor-like kinases and Stress responsive genes

I. Introduction

Natural environment is composed of a complex set of abiotic stresses and biotic stresses and plants are exposed to a wide range of these environmental stresses. Such stresses give rise to imbalances in the ability of a plant to perform normal metabolic processes (Marshall \textit{et al.}, 2012). Stress perception and plant response occurs via signal transduction pathways, regulates expression of several classes of stress responsive genes (srq-genes). The products of srq-gene include chaperones, osmotins, anti-freeze proteins, mRNA binding proteins, enzymes involved in osmolyte biosynthesis, water channel proteins, sugar and proline transport proteins, detoxification enzymes, a variety of proteases, proteins and protein kinases or receptor-like kinases (RLKs). Out of these srq-gene products, protein kinases (RLKs) are transmembrane proteins and play an important role in optimizing plant responses under different types of stress. They are considered as key regulators of plant architecture and growth behavior in stress conditions (such as regulation of many physiological changes in plants such as self-
incompatibility, endosperm and pollen development, brassinosteroid sensing, anthoptosis, disease resistance etc.)

In the eukaryotes, protein kinases (RLKs) make up a large super-family of homologous proteins, which are subdivided within the two super-family (i) Protein-serine/threonine kinases and (ii) Protein-tyrosine kinases. Serine/threonine protein kinase phosphorylate the OH groups of serine or threonine and been classified as Cyclin-dependent kinases (CDKs), Ca\(^{2+}\) calmodulin-dependent protein kinase-II (CaM kinase II or CaMKII), Mitogen activated kinases (MAPK), receptor like kinase (RLKs). The network of protein-serine/threonine kinases act as a “central processor unit” (CPU), accepting input information from receptors that sense environmental conditions, phytohormones, and other external factors, and converting it into appropriate outputs such as changes in metabolism, gene expression, and cell growth and division (Hanks and Hunter, 1995; Hardie, 1999).

Protein-tyrosine kinases, catalyze the phosphorylation of tyrosine residues in proteins and classified into two groups: (i) receptor tyrosine kinase (transmembrane proteins, which are involved in the control of animal cell growth and differentiation) and (ii) non receptor tyrosine kinase (lack transmembrane domains). Tyrosine- kinases function in many signal transduction cascades. In the cytosol, the nucleus, and the inner surface of the plasma membrane it act as critical component in the regulation of the immune system. Inside the nucleus tyrosine kinase is involved in cell cycle control. Elucidation of the functions of these kinases in different types of stress condition will provide a better understanding of stress-sensing mechanisms in plants and help to identify potential candidate genes for genetic engineering of improved stress-tolerant crops. In this review, we summarized very briefly the structure, classification, types and functions of different families of RLKs under different types of stress conditions.

II. Methodology

This review paper is prepared based on primary and secondary published materials of various sources.

III. Discussion

RLKs and its classification

Plant receptor-like kinases (RLKs) represents one of the largest gene families in the Arabidopsis genome, comprising at least 610 members (Shiu and Bleecker, 2001), with approximately 1,131 members in rice (Shiu et al., 2004). Size variations of the RLK families have been affected by many factors such as natural and artificial selection, living environments, genome size variation, polyploidization (Zhang, 2010). RLKs having amino-terminal extracellular domains and carboxyl-terminal intracellular kinase domains, with striking resemblance in domain organization to the animal receptor tyrosine kinases such as epidermal growth factor receptor. These ecto and endo domain parts are involved in downstream signal transduction. The ectodomain part is thought to act as a ligand-binding site. Their N-terminal signal sequence varies in structure, a single membrane-spanning region, and a cytoplasmic protein kinase catalytic domain. On the bases of variations in N-terminal sequences, plant RLKs are classified into the following six different classes, which performed different functions in plants:

(i) S-domain class, possess an extracellular S-domain homologous to the self-incompatibility-locus glycoproteins (SLG) of Brassica oleracea. It consists of 12 conserved cysteine residues, out of which ten are absolutely conserved. SLG protein of this class plays an important role in self-incompatibility recognition process between pollen and stigma, act as a receptor for the pollen-derived ligand and in plant defense response (Nasrallah, 2000; Pastuglia et al., 1997).

(ii) LRR (leucine-rich repeats) class: the largest class of plant RLKs, having tandem repeats of approximately 24 amino acids with conserved leucines. This class of RLKs plays an important role in plant development. For e. g. ERECTA regulates organ shape, CLAVATA1, HAESA and BRI1 regulates shoot meristem cell differentiation, floral abscission process and brassinosteroid perception respectively (Torii, 2000; Clark et. al., 1997; Li and Chory, 1997; Jinn et al., 2000). LRR-RLKs also play a role in disease resistance e. g. rice gene Xa21 confers race-specific resistance to
Xanthomonas oryzae cv. oryzae (Song et al., 1995), tomato C\textsubscript{f} disease resistance gene products confer a race-specific resistance to Cladosporium fulvum (Jones and Jones, 1996)

(iii) Tumor-necrosis factor receptor (TNFR) class having a conserved arrangement of six cysteines, and seven repeats of ~39 amino acids that display a weak similarity to the RCC GTPase. The maize CRINKLY4 (CR4) gene product possess TNFR like repeats. CR4 is required for a normal cell differentiation of the epidermis. The Arabidopsis genome contains several genes related to CR4 (Becraft et al., 1996; McCarthy and Chory, 2000)

(iv) The cell wall associated receptor kinases (WAKs) represent the EGF (epidermal growth factor) class. Motif of EGF is characterized by a conserved arrangement of six cysteine, play a role in protein-protein interactions, pathogenic responses (He et al., 1996; He et al., 1998).

(v) PR class, Arabidopsis PR5K (PR5-like receptor kinase) is the known example of this class. The extracellular domain of PR5K exhibits sequence similarity to PR5 (pathogenesis related protein 5), whose expression is induced upon pathogen attack (Wang et al., 1996). The structural similarity between the PR5K receptor domain and PR5 suggests a role for PR5K in pathogenesis response.

(vi) The Lectin RLK (LecRK) class, is believed to play crucial roles in saccharide signaling as well as stress perception (defense against various plant pathogens and pests). LecRLKs possess three domains: an N-terminal lectin domain, an intermediate trans-membrane domain, and a C-terminal kinase domain. On the basis of lectin domain variability, LecRLKs again sub grouped into three subclasses: L, G, and C type. Phylogenetic analysis has been shown that plant receptor-like kinases (RLKs) share an evolutionary origin with the animal interleukin-1 receptor-associated kinase (Klaus-Heisen et al., 2011). RLKs are again sorted in four main types, which are further divide in subfamilies (Table 01).

Types and subfamilies of RLKs
(a) LRR (leucine-rich repeat RLKs)
(b) PERK (proline-rich-extensin-like-RLKs)
(c) CRK/DUF26 (cysteine-rich RLK/ Domain of Unknown Function 26)
(d) RLCK (Calcium/calmodulin-regulated RLKs).

Leucine-rich repeat RLKs (LRR-family): LRR-RLKs involved mainly in water stress responses. Expression of LRR-RLK [a receptor-like protein kinase1 (RPK1)] is induced by ABA, dehydration, high salt, and low temperature. Loss of function of RPK1 resulted in ABA insensitivity and reduced expression levels of various water stress-responsive genes, indicating that RPK1 positively regulates ABA/stress signalling. In an independent study Lee et al. (2011) reported that RPK1 functions in ABA dependent leaf senescence as well. RPK2 controls cell fate in anthers (Mizuno et al., 2007), embryo development (Nodine et al., 2007), and stem cell homeostasis in the shoot apical meristem through the mediation of CLV3 (Kinoshita et al., 2010; Betsuyaku et al., 2011). These studies indicate that RPK2 is another important RLKs governing plant development in various species. RLK7, an LRR-RLK member of the LRR XI sub-family, was identified as an important regulator in oxidative stress responses and shown to be involved in maintaining seed longevity (Pitorre et al., 2010).

Recently, an LRR-RLK that controls ABA and H\textsubscript{2}O\textsubscript{2} regulated activation of S-type anion channels in guard cells has been identified (Hua et al., 2012). This RLK, named GUARD CELL HYDROGEN PEROXIDE-RESISTANT1 (GHR1), physically interacted with and activated the S-type anion channel SLOW ANION CHANNEL-ASSOCIATED1 (SLAC1) by phosphorylation, resulting in stomatal closing in response to drought stress.

Proline-rich-extensin-like-RLKs (PERK family): A member of the proline-rich extensin-like receptor kinase family, PERK4, was identified as a positive regulator in ABA responses (Bai et al., 2009). Decreased sensitivity to ABA with respect to seed germination, seedling growth, and root tip growth was observed in perk4 mutant plants. ABA-induced elevation of the concentration of cytosolic free calcium and Ca\textsuperscript{2+} channel activity were impaired in perk4 root cells. PERK4 was shown to be an ABA and Ca\textsuperscript{2+} activated protein kinase that functions at an early stage of ABA signaling, and this is involved in the inhibition of root cell elongation (Bai et al., 2009). All detail suggesting that PERK4 may
perceive changes in the levels of ABA.

**Cysteine-rich rlk/domain of unknown function 26 (CRK family):** The DUF26 (Domain of Unknown Function 26; PFAM domain PF01657) RLKs, also known as Cysteine-rich RLKs (CRKs), form a large subgroup of the RLK family with more than 40 members (Shiu and Bleecker, 2003; Chen et al., 2004). The extracellular region of the protein contains two copies of the DUF26 domain which has four conserved cysteines (three of them form the motif C-8X-C-2X-C) that may form disulphide bridges as potential targets for thiol redox regulation. The CRKs are transcriptionally induced by oxidative stress, pathogen attack and application of salicylic acid (SA) (Chen et al., 2003; Chen et al., 2004; Czernic et al., 1999).

**Calcium or calmodulin-regulated RLKs (RLCK family)**

Calcium-mediated signaling plays a pivotal role in plant responses to abiotic stresses, including cold and drought stress. Calcium/calmodulin-regulated RLCKs have been shown to be involved in abiotic stress signaling. For instance, the cold-responsive **CRKL1**, which encodes an RLCK with two sites for calcium/calmodulin binding to stimulate kinase activity, was reported to regulate cold stress signaling.
(Yang et al., 2010b). The crlk1 knock-out mutant plants exhibited an increased sensitivity to chilling and freezing stress, and cold-responsive genes were down-regulated in crlk1 mutants. Calcium-dependent calmodulin-binding RLCKs have also been isolated from Glycine max (GmCaMK1) (Defalco et al., 2010) and Glycine soja (GsCBRLK) (Yang et al., 2010a). GmCaMK1 and GsCBRLK activities are regulated by its calcium/calmodulin binding, and the overexpression of these genes in transgenic Arabidopsis enhanced plant tolerance to high salinity and ABA, as well as increasing the expression level of stress marker genes.

Functions of RLKS

RLKS and plant growth regulation: Kinases transfer phosphoryl groups onto target proteins and altering their activity. Protein phosphorylation or dephosphorylation is the basic of many critical processes, including enzyme activation or inactivation, protein localization and protein degradation signal transduction, cell differentiation, cell proliferation and cell cycle progression. Kinases act as receptors on the cell membrane. Activation of a cell surface transmembrane receptor kinase by its ligand leads to changes in gene transcription and cell response. A fundamental aspect of plant growth regulation is cell cycle control and this involves the activity of several receptors like kinases protein. The receptor like kinases GS01 and GS02 together regulate root growth in Arabidopsis through control of cell division (Racolta et al., 2013).

RLKS and environmental stress: RLKS have been known to have a major role in integrating environmental and plant hormone signalling (Dievart and Clark, 2004). Recent studies suggested that the rapid evolution and diversification of RLK-encoding genes in the plant genome might be enhanced by various environmental associations (Alcazar et al., 2010; Smith et al., 2011) (Table 02 & Table 03).

- RLKS convey signal to their target proteins in the cytoplasm by catalytic processes of protein kinase activity. RLKS like RPK1, CYSTEINE-RICH RLK, PROLINE-RICH-EXTENSIN-LIKE RLK4 (PERK4), and GHR1 (GUARD CELL HYDROGEN PEROXIDE-RESISTANT1) have been reported to control water stress signalling directly in Arabidopsis (Hua et al., 2012; Bai et al., 2009; Osakake et al., 2010).

- LRR-RKs regulate a wide variety of developmental and defense-related processes (host-specific as well as non-host-specific defense response, wounding response, and symbiosis). PNAS, SR160, a tomato LRR-RLK, has been identified as the receptor, involved in systemic wounding signalling.

- RLK7 (the leucine-rich repeat class of receptor-like kinase [LRR-RLKS]) is involved in the control of germination speed and the tolerance to oxidant stress (Pitorre et al., 2010).

- Lectin RLK (LecRLK) is believed to play crucial roles in saccharide signaling as well as stress perception. Over-expression of LecRLK has been demonstrated to improve germination rate, pigment content, and biochemical status of the salt-stress-affected plants (Deng et al., 2009; Sun et al., 2012). Stomatal closure is one of the most commonly employed defense mechanisms to limit the pathogen entry but this could result in a drop in CO2 uptake, thus negatively affecting plant physiology. The Arabidopsis LecRK-V.5 gene has been recently found to reverse the stomatal closure induced by bacterial infection and relieve the plant from CO2 deficiency (Arnaud et al., 2012). The potential role of LecRLK in symbiosis is evidenced in Medicago plants upon infection with Sinorhizobium melliloti (Navarro et al., 2003).

- RLKS also participate in the recognition of pathogen a virulence factors (Avr genes) produced by specific strains of plant pathogens (Lee et al., 2006). Recently a B-lectin RLK, termed Pi-d2, was identified as an R gene conferring resistance to the fungal pathogen Magnaporthe grisea (M. grisea) strain ZB15 (Chen et al., 2006).

- Chen et al., (2013) reported OsSIK2, an S-domain RLK from rice, play an important role in senescence process (in abiotic stress). Certain Cysteine-rich receptor kinases (CRK) proteins from Arabidopsis thaliana have been implicated in defense responses, for instance, over expression of Arabidopsis AtCRK5 was correlated with enhanced leaf growth and displayed enhanced resistance.
to bacterial pathogen *Pseudomonas syringae* through induction of expression of pathogenesis-related 1 (PR1) gene (Yang et al., 2010a; Wang et al., 1996).

**RLKs and BR signalling:** Like animal steroids, BRs are plant hormones required for normal plant growth, reproduction and development, as well as responses to both abiotic and biotic stresses (Divi and Krishan, 2009; Wolters and Jurgens, 2009; Wang, 2012). Plants that are deficient either in the biosynthesis or perception of these hormones are typically dark green dwarfs with epinastic leaves, have reduced or no fertility, and exhibit delay development (Bishop and Koncz, 2002). BRs negatively regulate stomatal development, mediated by upstream signalling components including the BR receptor RLK BRI1, the protein phosphatase BRI1 SUPPRESSOR1 (BSU1), the BR SIGNALLING KINASE 1 (BSK1), and the GSK3-like kinase BRASSINOSTEROID-INSENSITIVE 2 (BIN2) (Tang et al., 2008). BRs have also been shown to repress light-responsive gene expression and chloroplast development mainly through the BRASSINAZOLE RESISTANT 1 (BZR1)-mediated transcriptional network (Luo et al., 2010; Sun et al., 2010).

**IV. Conclusion**

Environmental stress tolerance is an important agronomic trait and is essential for maintaining high yield under adverse conditions. It is important to understand how plants sense the environment and regulate signaling networks. Genetic engineering of plant membrane signaling factors, including RLKs can have a positive impact on stress tolerance by influencing many downstream signaling factors, multiple functions and signaling networking of RLKs in stress conditions. This review explored how stress-specific 'ligands' of different types of RLKs coordinately control various molecular events and down-stream cascades, such as phosphorylation cascades, activation of secondary messengers, gene expression, protein dynamics, and the other functions of different families of RLKs in stress conditions.
